

# Fullstack Web Development Tutorial Lesson 18

#### Today's lesson will cover

- Modules
- Export and Import
- Dynamic imports

## JavaScript fundamentals

#### **Modules**

- As our application grows bigger, we want to split it into multiple files, so called "modules". A module may contain a class or a library of functions for a specific purpose.
- Modules can load each other and use special directives export and import to interchange functionality, call functions of one module from another one:
  - export keyword labels variables and functions that should be accessible from outside the current module.
  - import allows the import of functionality from other modules.
- As modules support special keywords and features, we must tell the browser that a script should be treated as a module, by using the attribute <script type="module">.
- Modules work only via HTTP(s), not in local files
  - o If you try to open a web-page locally, via file://protocol, you'll find that import/export directives don't work. Use a local web-server, such as static-server or use the "live server" capability of your editor, such as VS Code Live Server Extension to test modules.
- Build tools:
  - In real-life, browser modules are rarely used in their "raw" form. Usually, we bundle them together with a special tool such as Webpack and deploy to the production server.
  - One of the benefits of using bundlers they give more control over how modules are resolved, allowing bare modules and much more, like CSS/HTML modules.
  - Unreachable code removed.
  - Unused exports removed ("tree-shaking").
  - o Development-specific statements like console and debugger removed.

#### **Export and Import**

- We can put import/export statements at the top or at the bottom of a script, that doesn't matter. In practice imports are usually at the start of the file, but that's only for more convenience.
- Common types of export:
- Before declaration of a class/function/...: export [default] class/function/variable ...
- Standalone export: export {x [as y], ...}.
- Re-export:
  - o export {x [as y], ...} from "module"
  - export \* from "module" (doesn't re-export default).
  - export {default [as y]} from "module" (re-export default).
- Imports:
- Named exports from module: import {x [as y], ...} from "module"
- Default export:
  - o import x from "module"
  - o import {default as x} from "module"
- Everything: import \* as obj from "module"
- Import the module (its code runs), but do not assign it to a variable: import "module"
- Please note that import/export statements don't work if inside { . . . }.
- A conditional import, like this, won't work:

```
if (something) {
  import {sayHi} from "./say.js"; // Error: import must be at top level}
```

#### **Dynamic imports**

- Dynamic import() introduces a new function-like form of import that caters to those use cases.
   import (moduleSpecifier) returns a promise for the module namespace object of the requested module, which is created after fetching, instantiating, and evaluating all of the module's dependencies, as well as the module itself.
- To dynamically import a module, the import keyword may be called as a function. When used this way, it returns a promise also supports the await keyword.
- Dynamic imports work in regular scripts, they don't require script type="module".
- Although import () looks like a function call, it's a special syntax that just happens to use parentheses (similar to super ()).
- Static import and dynamic import () are both useful. Each have their own, very distinct, use cases. Use static imports for initial paint dependencies, especially for above-the-fold content. In other cases, consider loading dependencies on-demand with dynamic import ().

#### **Summary: Modules**

- A module is a file. To make import/export work, browsers need <script type="module">. Modules have several differences:
  - Deferred by default.
  - Async works on inline scripts.
  - To load external scripts from another origin (domain/protocol/port), CORS headers are needed.
  - Duplicate external scripts are ignored.
- Modules have their own, local top-level scope and interchange functionality via import/export.
- Modules always use strict.
- Module code is executed only once. Exports are created once and shared between importers.
- When we use modules, each module implements the functionality and exports it. Then we use import to directly import it where it's needed. The browser loads and evaluates the scripts automatically.
- In production, people often use bundlers such as Webpack to bundle modules together for performance and other reasons.

### Self Study Assignments

#### To Dos

- Create a game of Rock, Paper and Scissors using JS which works on console, or with interactive UI using HTML,
   CSS and JS however you prefer (If you are working on your own project where you are using JS already, feel free to ignore this task but please share the project update with Lena.)
- Continue freecodecamp (FCC) Javascript. Ideally finish before we resume after summer.
- Continue with FCC HTML, CSS lessons. Ideally finish all the lessons by end of this month.
- If you believe FCC exercises aren't the best for you as in if you are quite advanced already, please start working on your own project and reach out to mentors for help if needed.
